1. INTRODUCTION

Here is a template for a simple commutative diagram in tikz:

$$\begin{array}{ccc} X' & \xrightarrow{f'} & Y' \\ h' \downarrow & & \downarrow h \\ X & \xrightarrow{f} & Y \end{array}$$

Here is a template for an elaborate commutative diagram in tikz:

$$\begin{array}{ccccc}
 & & X'_\alpha & \xrightarrow{\phi'} & Y'_\alpha \\
 & \swarrow & \downarrow f' & \swarrow & \downarrow \psi \\
 X' & \xrightarrow{\quad} & Y' & & \\
 \downarrow \psi' & & \downarrow \phi & \downarrow h & \\
 & \swarrow & X_\alpha & \xrightarrow{\quad} & Y_\alpha \\
 & \downarrow f & & \swarrow & \\
 X & \xrightarrow{\quad} & Y & &
 \end{array}$$

15.1. Basic Definitions.

Definition 15.1 (Temperley-Lieb Algebra). Let τ be a complex number. The **Temperley-Lieb algebra** $\text{TL}_n(\tau)$ is generated by an identity 1 and generators e_1, \dots, e_{n-1} satisfying the relations

- $e_i^2 = \tau e_i$
- $e_i e_{i+1} e_i = e_i$
- $e_i e_j = e_j e_i, |i - j| > 1$

We can give a pictorial description of this algebra: we regard each generator e_i as corresponding to a diagram

$$\begin{array}{ccccccc} | & | & \cdots & | & \frown & | & | & \cdots & | \\ 1 & 2 & & i-1 & & i+2 & & & n \end{array}$$

and regard τ as corresponding to the “fugacity of a bubble.” We then multiply by composing vertically (with the rightmost element at the top), and “popping” bubbles to obtain a factor of τ :

$$\begin{aligned} e_i^2 &= \begin{array}{ccccccc} | & | & \cdots & | & \frown & | & | & \cdots & | \\ & & & & \text{pink circle} & & & & \end{array} \\ &= \cdot \begin{array}{ccccccc} | & | & \cdots & | & \frown & | & | & \cdots & | \end{array} \end{aligned}$$

Example 15.2 ($\text{TL}_3(\tau)$). When $n = 3$, we have generators $1 = \begin{array}{|c|} \hline | \\ \hline \end{array}$, $e_1 = \begin{array}{|c|} \hline \frown \\ \hline \end{array}$, and $e_2 = \begin{array}{|c|} \hline \frown \\ \hline \end{array}$. We also obtain

$$e_1 e_2 = \begin{array}{c} \frown \\ \frown \end{array}$$

and

$$e_2 e_1 = \begin{array}{c} \frown \\ \frown \end{array},$$

so that $\text{TL}_3(\tau)$ is 5-dimensional.

Proposition 15.3. *The dimension of TL_n is*

$$\dim \text{TL}_n = C_n = \frac{(2n)!}{n!(n+1)!},$$

the n th Catalan number.

15.2. Temperley-Lieb Algebras and the Yang-Baxter Equation. We can reinterpret the Yang-Baxter equation through the lens of Temperley-Lieb algebras. Let $\tau = -(q + q^{-1})$, $a(u) = qu - q^{-1}u^{-1}$, and $b(u) = u - u^{-1}$. We can then regard \check{R}_i as an element of the algebra obtained by adding u^\pm and v^\pm to $\text{TL}_n(\tau)$:

$$\check{R}_i(u) = a(u)1 + b(u)e_i \in \text{TL}_n(\tau)[u^\pm, v^\pm].$$

One can check that the equation

$$\check{R}_i(u)\check{R}_{i+1}(uv)\check{R}_i(v) = \check{R}_{i+1}(v)\check{R}_i(uv)\check{R}_{i+1}(u)$$

holds; we may thus interpret the Yang-Baxter equation as an identity in $\text{TL}_n(\tau)[u^\pm, v^\pm]$.

Via this identification, we can regard systems satisfying the Yang-Baxter equation as representations of this algebra $\text{TL}_n(-(q+q^{-1}))[u^\pm, v^\pm]$. We may obtain one such representation via the map

$$\phi : \text{TL}_n(-(q+q^{-1})) \rightarrow \text{End}((\mathbb{C}^2)^{\otimes n})$$

sending

$$e_i \mapsto I \otimes I \otimes \dots \otimes I \otimes \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & -q^{-1} & 1 & 0 \\ 0 & 1 & -q & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \otimes I \otimes \dots \otimes I,$$

where the matrix is located in the i and $i + 1$ coordinates.

One can check that this map respects the Temperley-Lieb relations, and that it induces a representation $\rho : \text{TL}_n(-(q + q^{-1}))[u^\pm, v^\pm] \rightarrow \text{End}((\mathbb{C}^2)^{\otimes n})$ sending

$$\check{R}_i(u) \mapsto I \otimes \dots \otimes I \otimes \begin{bmatrix} qu - q^{-1}u^{-1} & 0 & 0 & 0 \\ 0 & u(q - q^{-1}) & u - u^{-1} & 0 \\ 0 & u - u^{-1} & u^{-1}(q - q^{-1}) & 0 \\ 0 & 0 & 0 & qu - q^{-1}u^{-1} \end{bmatrix} \otimes I \otimes \dots \otimes I$$

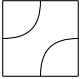

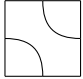

15.3. Loop Models.

Definition 15.4 (Loop Model). A **loop model** is an assignment of the tiles  and

to the $k \times n$ rectangle

We can compute the **fugacity** of a loop model with respect to a parameter $q \neq \pm 1$ by assigning a fugacity of $a(x_i/y_j)$ to the  tile, and $b(x_i/y_j)$ to the  tile, and multiplying by $\tau^{\# \text{ closed loops}}$, where $\tau = -(q + q^{-1})$. That is, the fugacity is

$$\tau^{\# \text{ closed loops}} \cdot \prod_{i=1}^k \prod_{j=1}^n \begin{cases} a(x_i/y_j) \\ b(x_i/y_j) \end{cases} \quad \begin{array}{c} \text{Diagram of a } 2 \times 2 \text{ grid of tiles with arcs} \end{array}$$

When $q = \pm 1$, we instead assign weights of $a(x_i - y_j)$ and $b(x_i - y_j)$ respectively, so that the fugacity of the loop model is

$$\tau^{\# \text{ closed loops}} \cdot \prod_{i=1}^k \prod_{j=1}^n \begin{cases} a(x_i - y_j) \\ b(x_i - y_j) \end{cases} \quad \begin{array}{c} \text{Diagram of a } 2 \times 2 \text{ grid of tiles with arcs} \end{array}$$

15.4. Loop Models and Grassmannians. Let $X = T^* \text{Gr}(k, n)$ be the cotangent bundle of the Grassmannian. We wish to consider its $T \times \mathbb{C}^\times$ -equivariant cohomology. Observe that

$$H_{T \times \mathbb{C}^\times}^*(X) \cong \mathbb{Z}[x_1, \dots, x_k, y_1, \dots, y_n, h]^{S_k} / \mathcal{I},$$

where:

- The ring $\mathbb{Z}[x_1, \dots, x_k, y_1, \dots, y_n, h]^{S_k}$ consists of polynomials symmetric in the x_i , i.e., invariant under the action of S_k on x_1, \dots, x_k .
- \mathcal{I} is the ideal generated by polynomials which vanish when each x_i is replaced by some (distinct) y_j . That is, for any $I \in \binom{[n]}{k}$, we can define a map

$$\phi_I : \mathbb{Z}[x_1, \dots, x_k, y_1, \dots, y_n, h]^{S_k} \rightarrow \mathbb{Z}[y_1, \dots, y_n, h]$$

which sends $p(x_1, x_2, \dots, x_k, y_1, \dots, y_n, h)$ to $p(y_{I_1}, y_{I_2}, \dots, y_{I_k}, y_1, \dots, y_n, h)$. Note that the order on the elements of I does not matter, since p is symmetric in the x_i . Then \mathcal{I} is the ideal generated by the kernels of the ϕ_I .

For example, when $k = 1$, we have that $\mathcal{I} = \langle (x_1 - y_1), (x_1 - y_2), \dots, (x_1 - y_n) \rangle$, so that

$$H_{T \times \mathbb{C}^\times}^*(\text{Gr}(1, n)) \cong \mathbb{Z}[x_1, y_1, \dots, y_n, h]^{S_k} / \mathcal{I}$$

Now, for each $I \in \binom{[n]}{k}$, let $X_I^\circ = B_- \mathbb{C}^I$, where \mathbb{C}^I is the coordinate subspace spanned by e_{I_1}, \dots, e_{I_k} , denote the Schubert cell corresponding to I . One can check that $X_I^\circ \cong \mathbb{C}^{k(n-k) - \text{inv}(I)}$, where $\text{inv}(I)$ is the inversion number of the binary string corresponding to I . In particular, X_I° is smooth.

Let $C_I = \overline{\mathbb{C}_{X_I^\circ} \text{Gr}(k, n)}$ denote the closure of the conormal bundle of X_I° in $T^*(\text{Gr}(k, n))$. Let $\tilde{S}_I = [C_I] \in H_{T \times \mathbb{C}^\times}^*(X)$ be the fundamental class of this conormal bundle.

Recall that when examining $H_T^*(\text{Gr}(\cdot, n))$, the T -equivariant cohomology of $\bigsqcup_{k=1}^n \text{Gr}(k, n)$, we assigned

$$S_I \mapsto \bigotimes_{i=1}^n \begin{cases} \begin{pmatrix} 1 & 0 \end{pmatrix}^{Tr} & i \notin I \\ \begin{pmatrix} 0 & 1 \end{pmatrix}^{Tr} & i \in I \end{cases}$$

In the case of the cotangent bundle, we attach an element of $(\mathbb{C}^2)^{\otimes n}$ to each \tilde{S}_I via **link patterns**. We begin with the binary string associated to I , and repeatedly attach links between each substring of 10, ignoring previously linked letters. This is perhaps most easily illustrated with an example: if our binary string is 01101001, the associated link pattern would be

To the link $i \frown j$ between positions i and j , we associate $\begin{pmatrix} 1 \\ 0 \end{pmatrix}_i \otimes \begin{pmatrix} 0 \\ 1 \end{pmatrix}_j - q^{-1} \begin{pmatrix} 0 \\ 1 \end{pmatrix}_i \otimes \begin{pmatrix} 1 \\ 0 \end{pmatrix}_j$, while to a “lonely” 0 or 1 in position i we associate $\begin{pmatrix} 1 \\ 0 \end{pmatrix}_i$ and $\begin{pmatrix} 0 \\ 1 \end{pmatrix}_i$ respectively. We then take the tensor product over the vectors associated to all links/lonely elements.

Theorem 15.5 (Z-J, [Loop Models and K-Theory](#), 2016). $\tilde{S}_I = [C_I]$ is equal to the loop model partition function on a $k \times n$ rectangle where the connectivity of the external points satisfy:

- No bottom points are connected to other bottom points
- No top points are connected to right points
- The top lines reproduce the link pattern of the associated binary string.
